13. ABSTRACT (Maximum 200 words)

A chiral dimethylpyridino-18-crown-6 ligand was attached to silica gel by first forming an allyloxy-substituted crown. This material was treated with triethyoxysilane and then coated and covalently attached to silica gel. This report shows the synthesis of the silica gel-bound chiral crown and its use in separating α-(1-naphthyl)ethylammonium perchlorate into its (R)- and (S)-forms.

The design, synthesis and use of macrocycles capable of selective recognition of other molecules is of great interest to workers in many fields. 1-3 Our interest is in the area of enantiomeric recognition and has focused on the interactions of chiral crown macrocycles with chiral organic ammonium cations. 4-10 We have chosen interactions of the chiral pyridino-18-crown-6 ligands because they form relatively strong complexes with the organic ammonium salts 11 and they can be prepared in the laboratory with various substituents on chiral positions on the macroring. We have made a systematic study of how the extent of enantiomeric recognition varies with crown substitutent, guest type and solvent. 6,7,10

We have now covalently attached chiral dimethylpyridino-18-crown-6 onto silica gel. More than a decade ago, Cram and coworkers covalently attached a different chiral crown ether to silica gel using another method, and they used this system for separation of the enantiomers of chiral organic ammonium salts.¹¹ This report describes the synthesis of chiral dimethyl-4-allyloxypyridino-18-crown-6 (1) (an analogue that can be bonded to silica gel) (see Scheme II) and its attachment to silica gel. A preliminary study of the separation of the (*R*)- and (*S*)-forms of NapEtClO₄ using the new silica gel-bound chiral crown (Scheme II) is also reported.

4-Allyloxy-2,6-pyridinedimethyl ditosylate, needed for the synthesis of the chiral crown (1) that is capable of being attached to silica gel, was prepared as shown in Scheme I. We have found that the use of powdered KOH in THF is a superior base-solvent system for the preparation of tosylates from alcohols and tosyl chloride.^{6,7,10}

New chiral macrocycle (S,S)-1 was prepared as shown in Scheme II. The

synthesis of silica gel-bound chiral dimethyl-substituted pyridino-18-crown-6 [(S,S)-9] is also shown in Scheme II. Starting (S,S)-dimethyltetraethylene glycol [(S,S)-7] was prepared as reported. The attachment of (S,S)-1 to silica gel was accomplished by first forming the chiral crown-triethoxysilane by a simple hydrosilylation reaction and heating this material in toluene in the presence of silica gel. The silica gel contained about 0.25 mmol of chiral crown per gram as determined by a combustion analysis.

A preliminary study on the separation of (R)- and (S)-NapEtClO₄ using silica gel-bound chiral crown **9** is shown in Figure 1. Racemic NapEtClO₄ was placed on a column containing (S, S)-**9**. The elution solvent was a mixture of 70% acetone and 30% CH₃OH by volume. We used acetone because, initially, we observed a high enantiomeric selectivity in pure acetone. This selectivity proved to be an artifact of the reaction of the ammonium salt with acetone to form a Schiff-base. The relative amounts of (R)- and (S)-NapEtClO₄ in each sample were determined from the HPLC chromatogram of the corresponding acetamide derivatives. Each fraction was treated with base and acetic anhydride. Blank determinations using known mixtures of the (R) and (S) salts and phthalimide as internal standard showed that this technique gave quantitative values for the amounts of the chiral salts in the sample.

As can be seen in Figure 1, (S,S)-9 does separate the (R)- and (S)-forms of NapEtClO₄. As expected, the (S)-form passes through the column first although it is contaminated by some of the (R)-form. (S,S)-9 interacts more strongly with (R)-NapEtClO₄ so that the (R)-form should come off the column last. This is a preliminary

experiment. This separation and that of other chiral organic ammonium salts need to be studied in greater detail. The incomplete separation of (S)-NapEtClO₄ could be caused by overloading the column or the use of the wrong solvent system.

It is possible that attachment to silica gel through the pyridine ring would put the steric portion of the chiral crown too close to the solid support. This could reduce the host-guest interaction and could change the degree of enantiomeric recognition.

Indeed, Schomburg and co-workers found that the chiral phase needed to be more than three atoms removed from the solid support for effective enantiomeric separation in supercritical fluid chromatography. Preliminary results using (*S,S*)-9 shown in Figure 1, indicate that there is recognition in this system. In the future, a chiral pyridino-crown similar to 9 but with a long chain spacer will be prepared, attached to silica gel, and tested.

Experimental Section

The ¹H NMR spectra were obtained at 200 MHz in CDCl₃ with TMS as the internal standard unless otherwise indicated. Melting points are uncorrected. Starting materials were used as purchased from Aldrich Chemical Company unless otherwise noted. Dimethyl 4-allyloxy-2,6-pyridinedicarboxylate (4),¹⁸ 4-allyloxy-2,6-pyridinedimethanol (5)¹⁸ and chiral dimethyl-substituted tetraethylene glycol (*S*,*S*-7)^{12,13} were prepared as reported. Chelidamic acid monohydrate (2) was made from chelidonic acid and concentrated NH₄OH as reported.¹⁹

Dimethyl Chelidamate (3) (Scheme I). Thionyl chloride (144 mL, 235 g,

2.0 mol) was slowly added to a stirred mixture of 71.8 g (0.36 mol) of 2 and 720 mL of CH₃OH in an ice-salt bath. The mixture was stirred in an ice-salt bath for 1 h and at rt for 2 days. The solvent was evaporated and the residue was mixed well with 750 mL of an 8% (w/v) NH₄O₂CCH₃ solution and stored in a refrigerator for 2 days. The white crystals were filtered, washed 3 times with 100-mL portions of cold water and dried. After recrystallization from CH₃OH, 66 g (88%) of pure 3 was obtained; mp 170-171 °C (lit.²⁰ mp 169-169.5 °C).

4-Allyloxy-2,6-pyridinedimethyl Ditosylate (6) (Scheme I). To a stirred suspension of 12.6 g (0.201 mol, 87.5%) of well powdered KOH in 45 mL of THF was added 8.8 g (0.045 mol) of 5 ¹⁸ dissolved in 120 mL of THF. After 10 min of stirring at 0 °C under Ar, 22.9 g (0.12 mol) of tosyl chloride dissolved in 120 mL of THF was added dropwise. After stirring the reaction mixture at 0 °C for 2 h and at rt for 4 h, the solvent was evaporated under reduced pressure. The residue was dissolved in a mixture of 1200 mL of CH₂Cl₂, 200 g of ice and 400 mL of water. The phases were mixed well and separated. The organic phase was dried (MgSO₄), filtered and the solvent was removed under reduced pressure to give 25.6 g of crude product. The product was recrystallized from a CICH₂CH₂CI-CH₃OH mixture to give 19.6 g (86%) of 6; mp 79-81 °C; IR (KBr) 1386, 1177 cm⁻¹, ¹H NMR δ 2.44 (s, 6 H), 4.50-4.58 (m, 2 H), 4.98 (s, 4 H), 5.29-5.48 (m, 2 H), 5.88-6.10 (m, 1 H), 6.82 (s, 2 H), 7.33 (d, 4 H, J = 10 Hz), 7.80 (d, 4 H, J = 10 Hz). Anal. Calcd. for C₂₄H₂₅NO₇S₂: C, 57.24; H, 5.00. Found: C, 57.41; H, 5.12.

19-Allyloxy-(4S,14S)-(+)-4,14-dimethyl-3,6,9,12,15-pentaoxa-21-azabicyclo [15.3.1] heneicosa-1(21),17,19-triene (1) (Scheme II). To a well stirred suspension of 2.0 g (66 mmol) of NaH (80% dispersion in mineral oil) in 40 mL of pure and dry THF at 0 °C under Ar was added dropwise 5.23 g (23.5 mmol) of (S,S)-7 dissolved in 220 mL of THF. The mixture was stirred at 0 °C for 10 min, at rt for 30 min and at reflux temperature for 3 h. The reaction mixture was cooled to -10 °C and 12.5 g (24.8 mmol) of 6 dissolved in 260 mL of THF was added dropwise. The resulting mixture was stirred at -10 °C for 20 min and then at rt for 36 h. After the reaction was complete, the solvent was evaporated under reduced pressure. The residue was dissolved in a mixture of 1000 mL of CH₂Cl₂, 100 g of ice and 200 mL of water. The resulting mixture was mixed well and separated. The aqueous phase was shaken twice with 200-mL portions of CH₂Cl₂. The combined organic phase was dried (MgSO₄), filtered and the solvent was removed under reduced pressure. The residue was purified on neutral alumina using toluene then C₂H₅OH/toluene (1/80) as eluents to give 5.42 g (60%) of 1 as a colorless oil; $[\alpha]_0^{22}$ + 26.88° (c = 1.40, CHCl₃); IR (neat) 3082, 1598, 1575, 1454, 1360, 1110, 1042 cm⁻¹; ¹H NMR δ 1.12 (d, 6 H, J = 7 Hz), 3.33-3.67 (m, 12 H), 3.68-3.87 (m, 2 H), 4.51-4.61 (m, 2 H), 4.72 (s, 4 H), 5.22-5.45 (m, 2 H), 5.88-6.11 (m, 1 H), 6.76 (s, 2 H); MS (low voltage), m/e 381 (M⁺). Anal. Calcd. for C₂₀H₃₁NO₆: C, 62.97; H, 8.19. Found: C, 62.88; H, 7.92.

Silica Gel-bound Chiral Crown 9 (Scheme II). A mixture of 1.06 g (2.78 mmol) of 1 and 0.77 mL (0.685 g, 4.1 mmol) of triethoxysilane (freshly distilled under Ar) was stirred vigorously in a 5-mL one-necked flask equipped with a rubber septum. Two drops of PC072 catalyst (hüls America, Inc.) was added through the rubber

septum. The hydrosilylation reaction was carried out as reported by Lewis.³⁰ After stirring the mixture for 6 days at rt, the ¹H NMR spectra showed that the olefin protons had disappeared. The volatile compounds were removed from the reaction mixture under vacuum (0.02 mm) and the residue (1.49 g, 98%) was stirred with 6.0 g of silica gel (Davison Chemical, pore diameter 150 Å, 60-200 mesh) in 100 mL of toluene at 90 °C for 2 days. After the reaction was completed, the silica gel was filtered and washed with toluene/methanol (1/1) and then with methanol. The filtrate was evaporated to give 0.47 g of unreacted organic material. This means that about 1.0 g (1.8 mmol) of crown was attached to the silica gel. The silica gel containing the crown was dried in a vacuum oven at 70 °C for 5 h. A sample of blank silica gel was dried the same way and it gave a combustion analysis of 0% C and 0.35% H. The combustion analysis of 9 gave C, 5.83; H, 1.16. This indicates that each gram of 9 contained 0.243 mmol (by %C) or 0.251 mmol (by %H) of the chiral crown.

Separation of the R-(+) and S-(-) Isomers of NapEtClO₄ Using (S,S)-9. The preparation of (R)-(+)- and (S)-(-)-NapEtClO₄ was described earlier.⁴ Pure (R)- and (S)-NapEtClO₄ were obtained by recrystallization from butyl acetate; (R)-NapEtClO₄; mp 184-185 °C, [α]₃₆₅+ 21.27° (c = 1, C₂H₅OH); (S)-NapEtClO₄; 183-184 °C; [α]₃₆₅ - 21.12° (c = 1, C₂H₅OH). (R)-NapEtClO₄ (40.0 mg) and 40.0 mg of (S)-NapEtClO₄ were dissolved in 8.0 mL of THF. (C₂H₅)₃N (50 μ L) was added to 2.0 mL of this solution and then 15 μ L of acetic anhydride was added and the mixture was stirred at rt for 10 min. TLC analysis (silica gel with CH₃CO₂C₂H₆/hexane (S)-NapEtClO as eluant) showed that a complete conversion of the perchlorate salt into the N-acetyl derivative

of α -(1-naphthyl)ethylamine had occurred. After evaporation of the solvent under reduced pressure, the residue was dissolved in a mixture of 20 mL of CH3CO2C2H5 and 20 mL of H₂O. The mixture was shaken well and separated. The organic phase was dried (MgSO₄), filtered and the solvent was evaporated to give 15.7 mg (100%) of N-[α -(1-naphthyl)ethyl]acetamide as white crystals; mp 158-159 °C; ¹H NMR δ 1.63 (d, 3 H, J = 6 Hz), 1.92 (s, 3 H), 5.80-6.00 (m, 2 H), 7.35-8.15 (m, 7 H); IR (KBr)3292, 1631, 1540, 1372, 1274, 1125, 965, 780, 609 cm⁻¹. The enantiomeric ratio was determined to be 50.24% (R) and 49.76% (S) by HPLC analysis on a chiral column as mentioned below. The remainder of the above THF solution (6.0 mL) was evaporated to give 60.0 mg of racemic NapEtClO4 which was dissolved in 1.0 mL of a CH₃OH/acetone (3/7) mixture and was placed onto the top of a column of 4.22 g of (S,S)-33 and eluted with the CH₃OH/acetone (3/7) mixture. The flow rate of the eluant was 0.088 mL/min. The amount of NapEtClO, salt in each 4-mL fraction was determined using the N-acetyl derivatization described above. The determination was performed on Hewlett Packard HP 1090 Liquid Chromatograph (Maximum pressure 300 ppsi, flow rate = 1 mL/min) using a chiracel ob chiral column (Daicel Chemical Industries, Ltd.). The internal standard was phthalimide. The HPLC solvent was 20% 2-propanol/80% n-hexane. The amount in milligrams of $(R)(m_p)$ - and (S)-NapEtClO₄(m_s) in each fraction was determined from peak areas as calibrated from known samples. The calculated concentrations of (R)- and (S)-NapEtClO4 were plotted versus the mL of eluant as shown in the smooth curve in Figure 1. Acknowledgment. This work was supported by the Office of Naval Research.
